

How Magvs answers a call: the six engines, in dispatch order

Tried in this order, each falls through to the next

Closed-form average

$\langle P \rangle$ in closed form

No trajectory is walked

An average is asked for,
and $\mathbb{H}$ does not vary

Adiabatic + Magnus

Smooth profile, a tolerance,
and it certifies itself

Interaction picture

Vacuum phase removed analytically, then one Magnus pass

Declared exponential, two flavors,
and its iteration converges

Energy-batched scan

$E_1 \dots E_n$

Many energies,
one baseline

(constant $\mathbb{H}$: one exact exponential instead)

Cumulative scan

One energy,
many baselines

$P(L_1), P(L_2), \dots$

General Magnus ladder

Anything else;
never skipped

One slab kernel,
three ways of batching
